It is mentioned in some resources that we can find the number of states in a Finite State Machine by using the method described below: I can't find the proof of any of these statements anywhere. So far, the only thing I can think of is the definition of a State, that is the combination of an initial State q_0 and the output on the current State q_i : $S_i = \{q_i\} \times \{l(q_i)\}$ where l is the output function. However, I can't find how this fact help in finding the number of states. Can someone please help me with this? A: You are correct that $S_i = \{q_i\} \times \{l(q_i)\}$
